## Restoring the natural habitat at Langlands Moss Local Nature Reserve

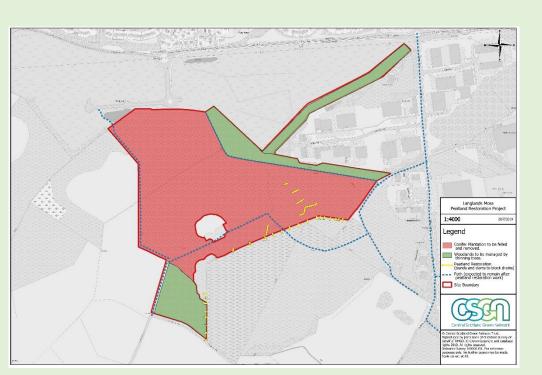

Conifers and drainage ditch at Langlands

Langlands Moss Local Nature Reserve, on the south edge of East Kilbride is set to be transformed. Site works during 2019 and 2020 will help to restore the natural bog and surrounding woodland habitats.

Phase one of planned works will improve the hydrology of the bog and its surroundings by removing the conifer plantation next to the bog. These trees were planted in the 1960s on deep peat, which would not be done nowadays. The conifers are now mature and a walk through the site will show that many of the trees have started blowing down already.

The conifer plantation will be removed in autumn/winter 2019 and all the material (tree trunks, branches and brash) will be taken away from the site to prevent the addition of nutrients to the sensitive habitat.

Langlands Moss will be closed to the public while the conifer trees are being removed. This is necessary for public safety, as there will be large machinery and stacked timber on site. Keep an eye on the Countryside Rangers and Friends of Langlands Moss Facebook pages, as well as signage on site to find out more.

Central Scotland

Green Network Trust

The boundary for the LNR is set to change as well, doubling the size of the site; the area which is currently wooded will officially become part of the nature reserve.

Once the trees have been removed and the site reopened, the main access routes shown on the map (blue dotted lines) should be available again for use. We expect that parts of the site will become wetter over the next couple of years which may affect some paths. Phase 2 of this project will involve sourcing funding to improve the access network in around Langlands Moss over the next few years.

We will also be using Scottish Natural Heritage's Peatland Action Fund to improve the hydrology of the main bog and surrounds by installing dams and bunds on existing drains (yellow lines on the map). Keeping more water in the bog will help it to function properly.

Over the next few years, we expect the land to green up with grasses starting to grow, followed by trees such as birch. In the longer term the area will convert to a wet woodland, similar to that at Mossneuk in East Kilbride. Part of this site also had conifer trees removed in 2005 and has returned to a natural wet woodland with heather and sphagnum mosses.
